Definition

In a patient with ILD of known or unknown etiology other than IPF who has radiological evidence of pulmonary fibrosis, PPF is defined as at least two of the following three criteria occurring within the past year with no alternative explanation:

1 Worsening respiratory symptoms

2 Physiological evidence of disease progression (either of the following):

a. Absolute decline in FVC >5% predicted within 1 yr of follow-up

b. Absolute decline in DLCO (corrected for Hb) >10% predicted within 1 yr of follow-up

3. Radiological evidence of disease progression (one or more of the following):

a. Increased extent or severity of traction bronchiectasis and bronchiolectasis

b. New ground-glass opacity with traction bronchiectasis

c. New fine reticulation

d. Increased extent or increased coarseness of reticular abnormality

e. New or increased honeycombing

f. Increased lobar volume loss

Raghu G et al, Idiopathic Pulmonary Fibrosis (an Update) and Progressive Pulmonary Fibrosis in Adults: An Official ATS/ERS/JRS/ALAT Clinical Practice Guideline. Am J Respir Crit Care Med. 2022 1;205(9):e18-e47.

Evolution of criteria in PPF

First author, year, reference	Type of proposal	Criteria of progression	Time period within which progression is assessed
Cottin (2018) [9]	ILD expert statement. Clinical practice.	Relative decline of at least 10% in FVC a relative decline of at least 15% in DLCO or worsening symptoms or a worsening radiological appearance accompanied by a at least 5 to less than 10% relative decrease in FVC	Within a 24-month period
George (2020) [35]	ILD expert statement. Clinical practice.	Relative decline of 10% or more in FVC Relative decline in FVC of 5% or more with decline in DLCO of 15% or more Relative decline in FVC of 5% or more with increased fibrosis on high-resolution CT (HRCT)* Relative decline in FVC of 5% or more with progressive symptoms Progressive symptoms with increased fibrosis on HRCT*	Over 24 months
Flaherty (2019) [24▪▪]	INBUILD clinical trial	Relative decline in FVC at least 10%; or FVC at least 5 to less than 10% and worsening of respiratory symptoms or increased extent of fibrosis on HRCT; or worsening of respiratory symptoms and increased extent of fibrosis on HRCT	Within 24 months
Maher (2020) [36▪]	U-ILD clinical trial	Either more than 5% absolute decline in FVC or significant symptomatic worsening	Within the previous 6 months

Valenzuela C et al, Epidemiology and real-life experience in progressive pulmonary fibrosis. Curr Opin Pulm Med. 2022;1;28(5):407-413.

Behr (2021) [37]	RELIEF clinical trial	Annualized percentage predicted FVC decline at least 5% (absolute)	Within up to 24 months
Raghu 2022 [11▪▪]	International guidelines ATS/ERS/JRS/ALAT	1. Worsening respiratory symptoms; 2. Physiological evidence of disease progression, either of the following: a. Absolute decline in FVC >5% predicted b. Absolute decline in DLCO (corrected for Hb) >10% predicted and 3. Radiological evidence of disease progression, one or more of the following: a. Increased extent or severity of traction bronchiectasis and bronchiolectasis b. New ground-glass opacity with traction bronchiectasis c. New fine reticulation d. Increased extent or increased coarseness of reticular abnormality e. New or increased honeycombing f. Increased lobar volume loss	Within 1 year of follow-up

- The above criteria mentioned are chosen based on the 5 years transplant free survival (TFS)

- Most of these datas are from the IPF studies.

Pugashetti, J.V. et al, *American Journal of Respiratory and Critical Care Medicine, 207* (1), 69-76.

- Dissecting the criteria used for PPF diagnosis, each component of the composite criteria by itself predicts the transplant free survival by itself.

- FVC relative decline ≥ 10% or DLco decline ≥15% and CT chest progression of fibrosis in the absence of FVC decline ≥ 10% better predicted the transplant free survival at 5 years.

- DLco as a isolated criteria for TFS is confounded by pulmonary vasculopathy.

- Using clinical symptoms alone for predicted TFS at 5 years has poor yield for prediction.

Pugashetti, J.V. et al, *American Journal of Respiratory and Critical Care Medicine, 207* (1), 69-76

- Time period for identification of disease progression in most trials is 2 years.

- However, if there is clear cut evidence that the disease is progressing at 3,6,9,12,24 or even 36 months, then one need not wait for the time period criteria to fulfil to call it as a progressive fibrotic ILD.

- The timelines for the criteria need not to be fulfilled to start treatment if the other criteria are clearly satisfied.

Cottin, V. et al, *American Journal of Respiratory and Critical Care Medicine, 206* (10), 1293-1294.

- Prevalence of PPF varies from 18 to 32% globally.
- Prevalence of CTD related ILD progressing to PF-ILD is more compared to other ILD(38.7%) ascertained from various studies.
- The incidence of PPF increases as the age increases.
- “Progression of ILD despite appropriate management qualifies the term “progressive pulmonary fibrosis”

Copeland CR and Lancaster LH (2021) Management of Progressive Fibrosing Interstitial Lung Diseases (PF-ILD). Front. Med. 8:743977.

Treatment overview

- **Pharmacological**
  - Antifibrotic agents – nintedanib, pirfenidone
  - Immunosupressants
  - Vasodilators
  - Anti-reflux therapy
- **Non-pharmacological**
  - Removal of triggers
  - Oxygen therapy
  - Lung transplantation
  - Vaccination – Influenzae, Pneumococcal vaccination.
  - Pulmonary rehabilitation

Efficacy of antifibrotic drugs, nintedanib and pirfenidone, in treatment of progressive pulmonary fibrosis in both idiopathic pulmonary fibrosis (IPF) and non-IPF: a systematic review and meta-analysis

James Patrick Finnerty[1,2*], Aravind Ponnuswamy, Prosjenjit Dutta[1], Ammar Abdelaziz[3] and Hafiz Kamil[1]

Finnerty JP et al, Efficacy of antifibrotic drugs, nintedanib and pirfenidone, in treatment of progressive pulmonary fibrosis in both idiopathic pulmonary fibrosis (IPF) and non-IPF: a systematic review and meta-analysis. BMC Pulm Med. 2021 11;21(1):411.

- Total of 13 studies were included. 4 studies were that of non-IPF progressive fibrosis studies.
- 54%(1564/2872) in IPF population and 50%(647/1292) in the non-IPF population were on some immunosupressants.
- FVC decline were similar in the IPF and Non-IPF group. The overall effect size is <0.30.
- Mortality benefit was observed in the IPF group but was not observed in the Non-IPF group.

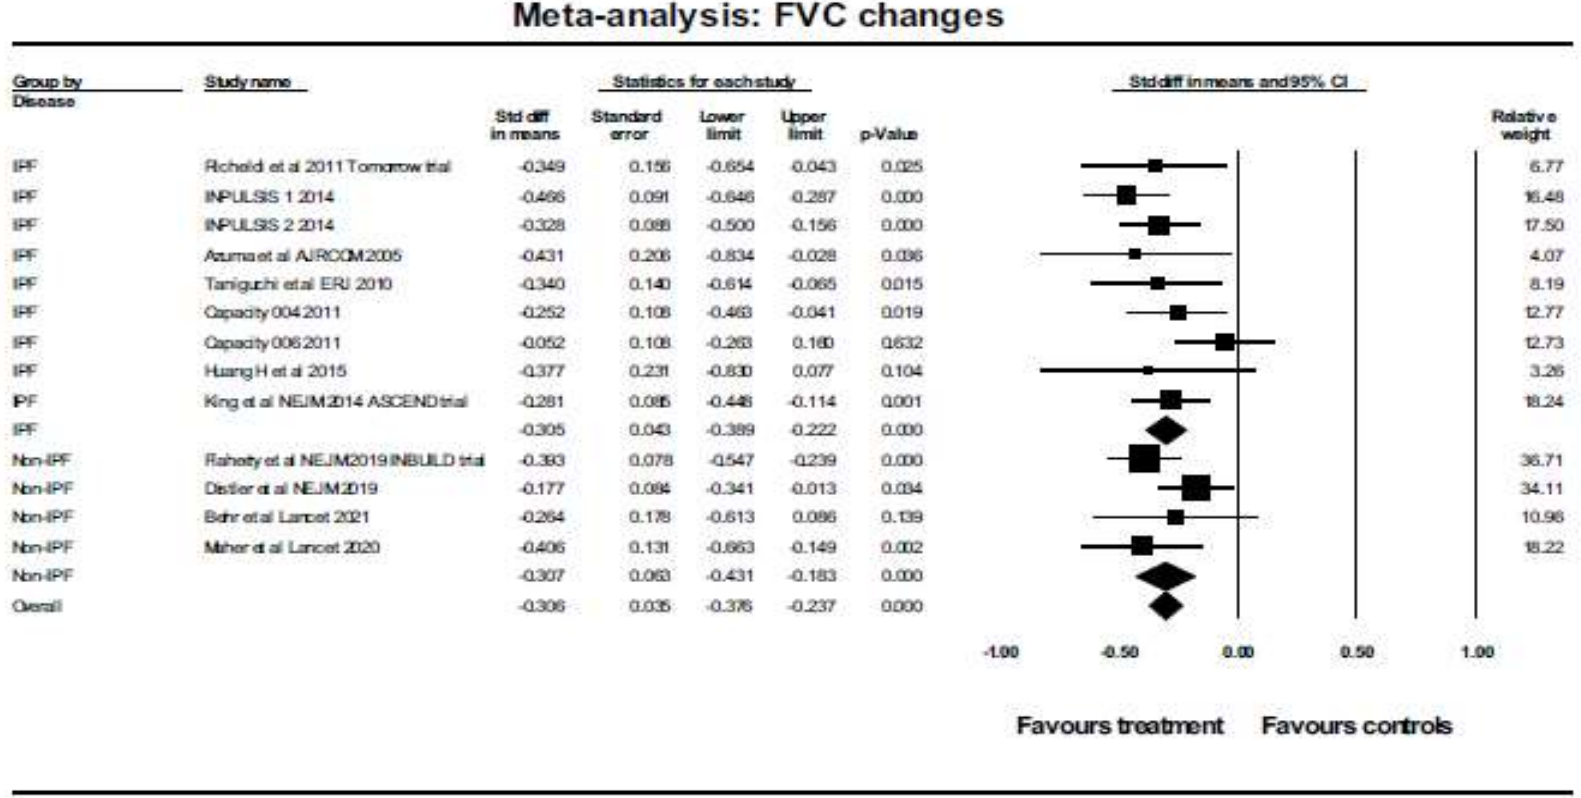

Fig. 4 Comparison of two groups of studies: IPF versus non-IPF for standardised FVC change in response to therapy

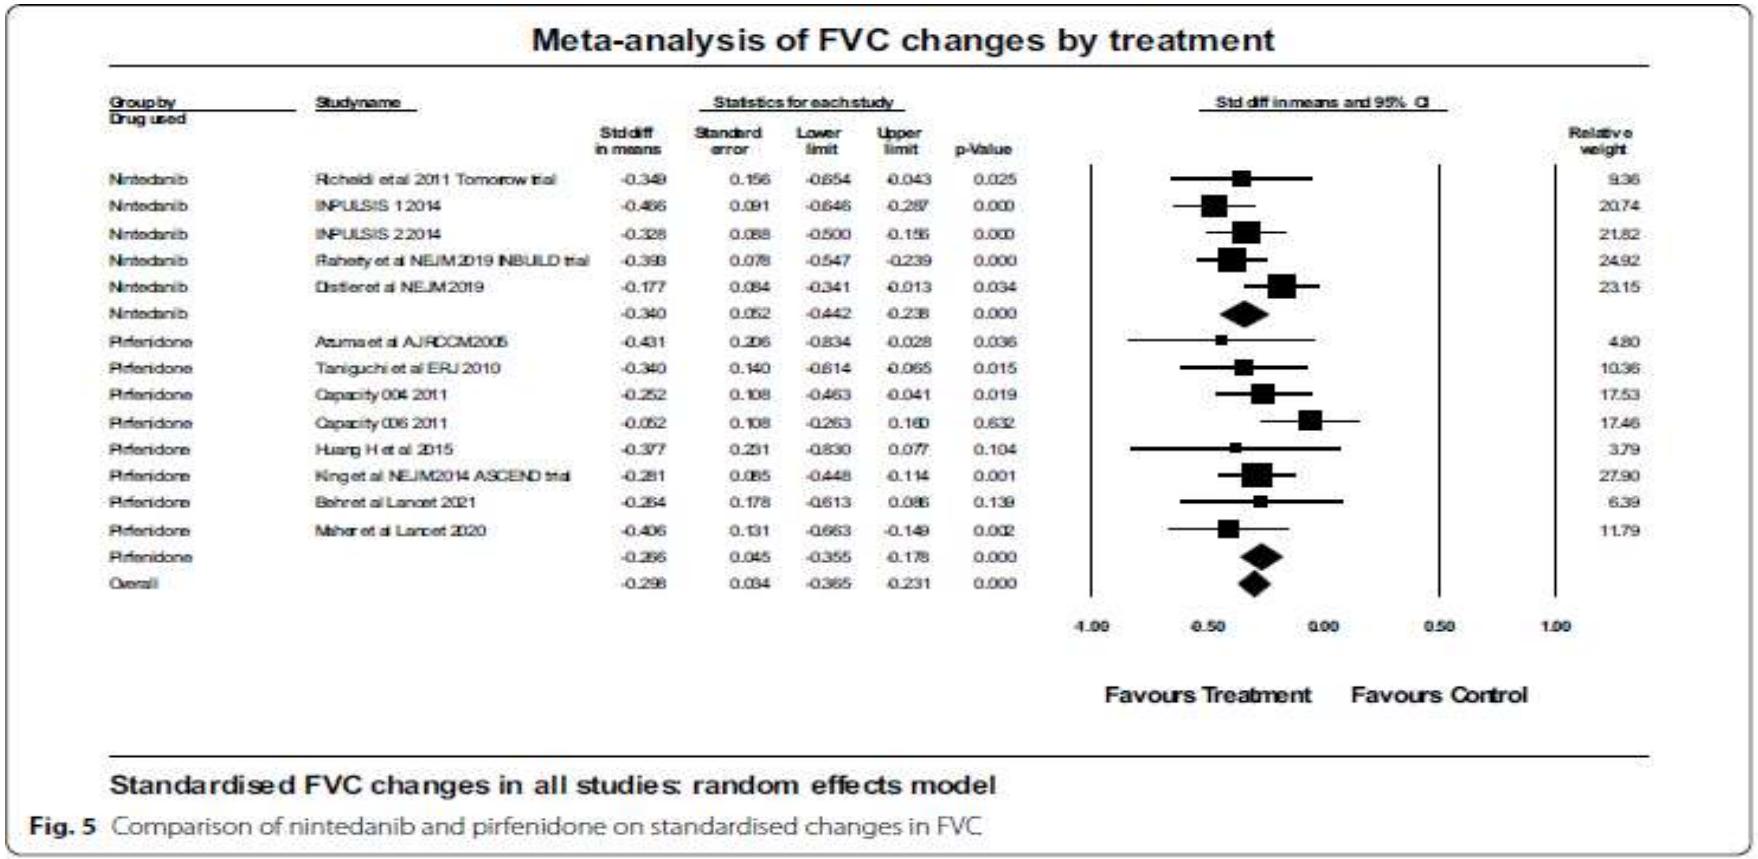

Fig. 5 Comparison of nintedanib and pirfenidone on standardised changes in FVC

Effect size with nintedanib was -0.34 and with pirfenidone was -0.26 with p value <0.001

Favors Control
Favors Nintedanib
Mean Difference [95% CI]

- Radiological UIP like pattern has better response to nintedanib than radiological non-UIP pattern.(2/3rd of 663 patients)

- Fibrotic HP, fibrotic sarcoidosis and unclassified ILD are poorly responsive to nintedanib (however the sample size of these ILD subtypes are small)

- Nintedanib does not have influence on time to first exacerbation or any mortality benefit.

Headache	35 (10.5)	23 (6.9)
Alanine aminotransferase increased	43 (13.0)	12 (3.6)
Progression of interstitial lung disease†	16 (4.8)	39 (11.8)
Weight loss	41 (12.3)	11 (3.3)
Aspartate aminotransferase increased	38 (11.4)	12 (3.6)
Abdominal pain	34 (10.2)	8 (2.4)
Severe adverse event§	60 (18.1)	73 (22.1)
Serious adverse event¶	107 (32.2)	110 (33.2)
Fatal adverse event		
Any	11 (3.3)	17 (5.1)
Any except for progression of interstitial lung disease†	10 (3.0)	14 (4.2)
Adverse event leading to treatment discontinuation	65 (19.6)	34 (10.3)
Adverse event leading to permanent dose reduction	110 (33.1)	14 (4.2)

Dose: 150 mg twice daily, in case of adverse effects it can be reduced to 100 mg twice daily

Adverse effects: most commonly diarrhoea and deranged liver function tests.

SYSTEMATIC REVIEWS

Pirfenidone in Progressive Pulmonary Fibrosis

A Systematic Review and Meta-Analysis

Marya Ghazipura[1,2], Manoj J. Mammen[3], Brittany D. Bissell[4,5], Madalina Macrea[6], Derrick D. Herman[7], Stephanie M. Hon[8], Fayez Kheir[9], Yet H. Khor[10,11], Shandra L. Knight[12], Ganesh Raghu[13], Kevin C. Wilson[14], and Tanzib Hossain[15]

Ghazipura M et al, Pirfenidone in Progressive Pulmonary Fibrosis: A Systematic Review and Meta-Analysis. Ann Am Thorac Soc. 2022;19(6):1030-1039..

- Included 2 studies (RELIEF trial and uILD). Total patients included – 380.
- Studies did not perform subgroup analysis of ILD subtypes for the outcomes neither differentiated the radiological pattern into UIP or non-UIP pattern.
- RELIEF trial which ended prematurely due to slow recruitment (because of strict enrolment criteria) has many imputed values, which makes the study as low evidence based.
- There were no mortality benefit found in this meta-analysis with pirfenidone (sample size small, follow up period is less).

Study (Reference)	Year	Location	Funding	Duration	PPF Diagnostic Criteria	ILD Subtypes	Study Population	Intervention	Comparator	Study Outcomes	Risk of Bias

Pirfenidone in patients with progressive fibrotic interstitial lung diseases other than idiopathic pulmonary fibrosis (RELIEF): a double-blind, randomised, placebo-controlled, phase 2b trial

Jurgan behr et al, *Lancet Respir Med 2021; 9: 476–86*

Study design	Inclusion criteria	Intervention	End points
Randomized double blinded placebo controlled multicentre trial 127 participants included	Adults 18-80 years of age Diagnosis of connective tissue diseaseassociated-ILD, fibrotic non-specific interstitial pneumonia, chronic hypersensitivity pneumonitis, or asbestos-induced lung fibrosis DLCO 25% to 75%(amended 10 to 90%) FVC 40% to 90% predicted	1:1 randomization to either placebo or pirfenidone	PRIMARY ENDPOINT: Absolute change in percentage of predicted FVC from baseline to week 48

Secondary End Point:

progression-free survival

Categorical assessment of relative changes from baseline to week 48 in predicted FVC of less than 5%, 5% to less than 10%, and atleast 10%

DLco

Exercise capacity (6-min walk distance
[6MWD])

Quality of life (St George's Respiratory Questionnaire [SGRQ]), time to clinical deterioration

Safety (frequencies of adverse events and serious adverse events).

Mycophenolate	7 (11%)	6 (10%)

Data are mean (SD) or n (%). DLCO=diffusing capacity of the lung for carbon monoxide. FVC=forced vital capacity. 6MWD=6-min walk distance. *n=14. †n=20.

***Table 1*: Baseline demographic characteristics in the safety analysis population**

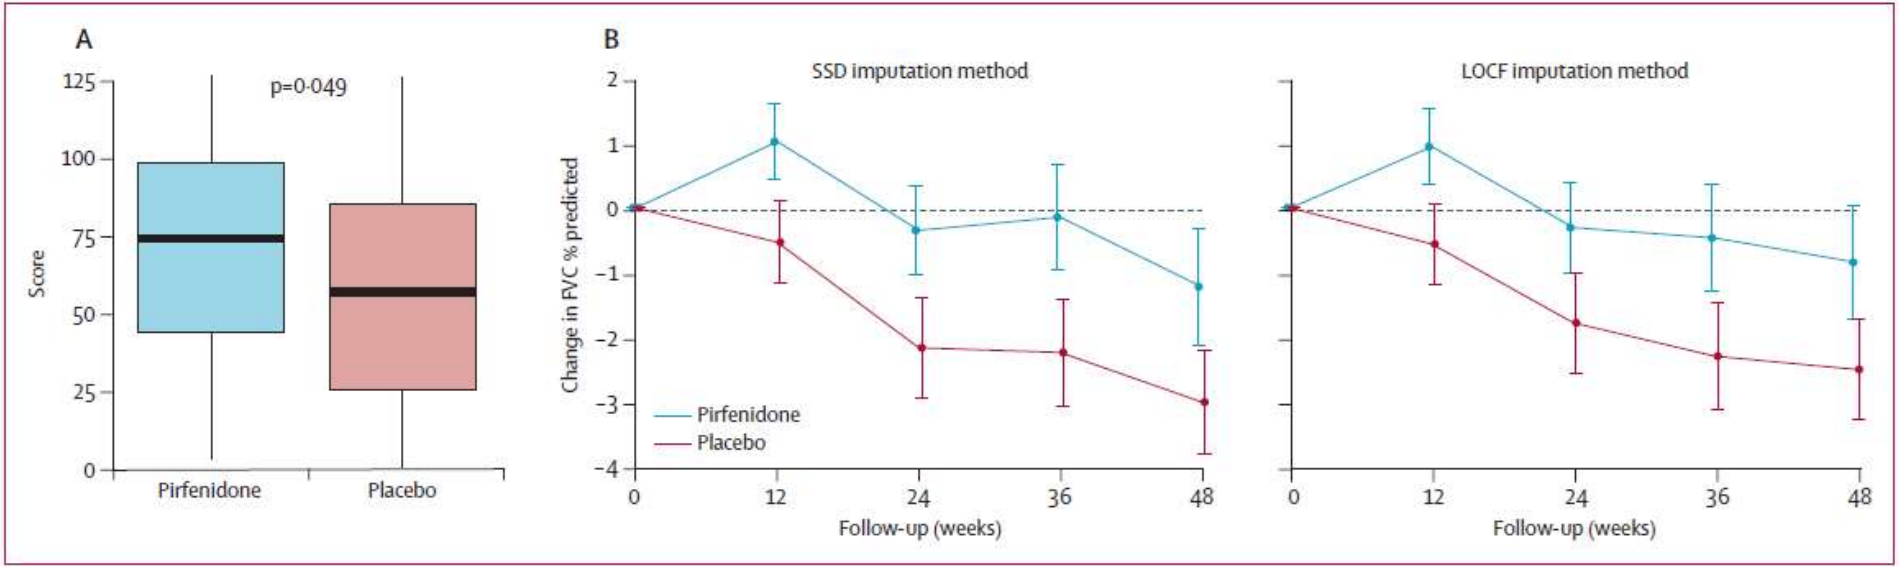

Figure 2: **Absolute change in percentage of predicted FVC and time course for mean change in percentage of predicted FVC from baseline to week 48**

(A) Distribution of Wilcoxon scores (from Mann-Whitney *U* test) for the absolute change in percentage of predicted FVC (FVC % predicted) from baseline to week 48 in the intention-to-treat population (n=127) for the pirfenidone and placebo groups (using the prespecified SSD imputation method for missing data, with deaths ranked worst). (B) Mean changes from baseline in FVC % predicted (SE) over the 48-week trial period in the pirfenidone and placebo groups after imputation of missing values (including those of deceased patients) according to the prespecified SSD method or, alternatively, the post-hoc LOCF imputation method. FVC=forced vital capacity. LOCF=last observation carried forward. SSD=sum of squared differences.

	Baseline				Change from baseline to week 48: within groups				Change from baseline to week 48: pirfenidone vs placebo	p value
	n	Pirfenidone	n	Placebo	n	Pirfenidone	n	Placebo		
FVC, mL	64	2332·5 (798·9)	63	2123·0 (715·7)	35	−36·6 (281·5)	32	−114·4 (225·3)	80·0 (−40·0 to 210·0)	0·21
DLCO, mmol/kPa per min	64	3·4 (1·4)	63	3·2 (1·2)	32	−0·1 (1·0)	26	−0·4 (0·6)	0·4 (0·1 to 0·7)	0·023
6MWD, m	64	357·7 (99·2)	63	345·2 (110·0)	33	−2·7 (74·2)	30	−34·1 (91·0)	28·0 (−15·0 to 75·0)	0·15
TLC, L	64	4·1 (1·2)	63	4·0 (1·0)	35	−0·1 (0·5)	32	−0·3 (0·4)	0·2 (0·0 to 0·4)	0·089
FEV_1, mL	64	2004·2 (636·2)	63	1761·7 (552·2)	35	−76·9 (259·3)	32	−103·1 (182·1)	50·0 (−50·0 to 140·0)	0·27

All analyses were done without imputation of missing values. Data are means (SD) at baseline, mean absolute changes (SD) from baseline to week 48, Hodges-Lehmann estimates for median differences (asymptotic 95% CIs) between pirfenidone and placebo, and two-sided p values from Mann-Whitney *U* tests. Note that FVC, TLC, and FEV_1 were assessed in post-hoc analyses. DLCO=diffusing capacity of the lung for carbon monoxide. FVC=forced vital capacity. TLC=total lung capacity. 6MWD=6-min walk distance.

- This trial ended prematurely due to strict enrolment criteria.
- Missing values are imputed for the analysis of outcomes. Therefore the evidence is low based.
- More study participants were on immunosupressants in baseline compared to that of INBUILD trial.
- FVC decline in pirfenidone group has not achieved a statistically significant value due to the above reason (p value >0.05).

Pirfenidone in patients with unclassifiable progressive fibrosing interstitial lung disease: a double-blind, randomised, placebo-controlled, phase 2 trial

Multicentre, double blind randomized placebo controlled phase 2 trial.

253 patients were included.

Duration was 24 weeks.

Maher et al, the lancet 2020; 8; P147-17

Inclusion Criteria:

Age 18 -85 years.

Fibrosing unclassifiable ILD as diagnosis after multidisciplinary discussion

Predicted FVC >45%

Predicted DLco >30%

>10% fibrosis in HRCT chest in previous 12 months

6 min walk test of minimum 150 metres

FEV1/FVC ratio >0.7

Progressive disease (>5% absolute decline in percent predicted FVC or symptomatic worsening not due to cardiac, pulmonary(other than disease progression) vascular or other causes

End point

Primary endpoint:

Predicted mean change in FVC from baseline over 24 weeks (daily home spirometry)

Secondary endpoint:

Change in FVC from baseline measured by spirometry during clinic visits.

Proportion of patients having >5% or >10% absolute or relative decline in %predicted FVC(site spirometry)

Change in %predicted DLco from baseline

Change in 6MWD from baseline

Change in university california san diego-shortness of breath questionnaire score

Change in leicester cough questionnaire score from baseline

Proportion of patients having all-cause and respiratory non-elective hospital admission

Incidence of, and time to first, investigator-reported acute exacerbation

Progression free survival

Treatment-related treatment-emergent adverse events known to be associated with pirfenidone		
Gastrointestinal disorder‡	60 (47%)	32 (26%)
Photosensitivity§	10 (8%)	2 (2%)
Rash¶	13 (10%)	9 (7%)
Dizziness	10 (8%)	4 (3%)
Weight decrease	10 (8%)	1 (1%)
Fatigue	16 (13%)	12 (10%)

In this study, primary pre-specified end point could not be analysed due to implausible data measured by home spirometry.

However, the secondary end points were met and it showed pirfenidone is better than placebo in terms of reducing FVC decline, improving 6MWD and reducing DLco decline.

Treatment benefit was generally observed with pirfenidone regardless of age, sex, lung function, and presence or absence of interstitial pneumonia with autoimmune features.

This study predominately included unclassified-ILD, some of the unclassified-ILD were labelled without biopsy (biopsy could have grouped these ILD into the existing groups).

The short duration of study (24 weeks) in this study, by nature cannot predict the long term outcome.

Real-world impact of antifibrotics on prognosis in patients with progressive fibrosing interstitial lung disease

Takayuki Niitsu ,[1] Kiyoharu Fukushima,[1,2] Sho Komukai,[3,4] So Takata,[1] Yuko Abe,[1] Takuro Nii,[5] Tomoki Kuge,[1] Shinichi Iwakoshi,[6] Takayuki Shiroyama,[1] Kotaro Miyake,[1] Kazuyuki Tujino,[2] Satoshi Tanizaki,[1] Kota Iwahori,[1] Haruhiko Hirata,[1] Keisuke Miki,[2] Masahiro Yanagawa,[7] Noriyuki Takeuchi,[8] Yoshito Takeda,[1] Hiroshi Kida,[2] Atsushi Kumanogoh[1]

Multicentre retrospective observation study

167 PF-ILD (Non-IPF 103) patients were included

Main groups were antifibrotic group and non fibrotic group among IPF and Non-IPF patients.

Non-IPF more than IPF patients were receiving baseline immunosupressive therapy.

Outcome assessed was FVC decline and overall survival.

Niitsu T, Fukushima K, Komukai S, et al. Real-world impact of antifibrotics on prognosis in patients with progressive fibrosing interstitial lung disease. RMD Open 2023;9:e002667

- Retrospective nature of the study, there a risk of selection bias and confounding factors.
- Any benefit of antifibrotic therapy is masked by immunosupressant medications.
- There is no uniformity in the starting of antifibrotic drugs, being a observational study.

Available immunomodulatory therapies

Corticosteroids

Mycophenolate mofetil

Cyclophosphamide

Rituximab

Corticosteroids

Sarcoidosis, crytogenic organising pneumonia, acute hypersentivity pneumonitis and eosinophilic pneumonia generally responds well.

Prednisolone may be used in Ssc related ILD, but the risk of scleroderma related renal crisis when dose >15mg/day particularly in early diffuse disease. Usually steroids are used in combination with other immunosupressants.

No trial evidence for SLE-ILD. Treatment consists of corticosteroids along with other immunosupressants.

IIM-ILD responds well to steroids(First line therapy).

Labirua-Iturburu, 2013	ARS	42	4/11	ATS criteria	CsA, Tacrolimus	Tacrolimus: oral, twice daily 0.065 mg/kg. Cyclosporine: oral, twice daily 2–5 mg/kg.
Marie, 2013‡	ARS (anti-PL7)	60	7/8	ATS criteria	CS alone, AZA, CYC	CS 1 mg/kg/day AZA 2 mg/kg/day CYC 0.7 g/m^2/month (6 pulses) MMF (30 mg/kg/day).
Marie, 2013‡	ARS (anti-Jo1)	55	25/41	ATS criteria	CS alone, AZA, CYC	CS 1 mg/kg/day AZA 2 mg/kg/day CYC 0.7 g/m^2/month (6 pulses) MMF (30 mg/kg/day)

T. Barba et al. Autoimmunity Reviews 18 (2019) 113–122

Prednisolone is started as 0.5 to 1 mg/kg/day (max 60 mg/day) for 1 month, then followed by 30 to 40 mg/day for next 2 months, then gradually tapered to 5 to 10 mg/day by the end of 6 months.

In a responding patient, treatment should be continued for atleast 1 year before stopping.

Elizabeth A et al, Respirology 2016;21(2):259-68.
up-to-date

Mycophenolate mofetil

MMF is a prodrug of mycophenolic acid, which is noncompetitive selective reversible inhibitor of inosine monophosphate dehydrogenase in stimulated lymphocytes.

It has anti-inflammatory, anti-proliferative and anti-fibrotic properties.

Gastrointestinal and bone marrow suppression are the most observed AEs and are mostly dose dependent and typically occur early in the course of treatment and decrease in frequency with continued use

The optimal daily dose range of MMF is 1.5–3 g in two divided doses. In patients with end-stage renal disease, dose reduction is recommended.

It should be taken either 30 minutes before a meal or 2 hours after the meal. Use of antacids and mineral supplements should be separated by at least 2 hours from time of intake of MMF.

Kevin K Brown et al, The emerging role of mycophenolate mofetil in interstitial lung diseases, Expert Review of Respiratory Medicine, 2021; 15:12, 1539-1549

Authors	No. of Patients	Design	Treatment Duration	FVC		DLco		Steroid Dose (mg)

Rituximab

Monoclonal antibody targeting CD20 on B-lymphocytes.

Mainly used in CTD-ILD.

Can be used as rescue therapy in patient of treatment refractory fibrosing ILD.

Xu L, Wang F and Luo F (2022), Rituximab for the treatment of connective tissue disease–associated interstitial lung disease: A systematic review and meta-analysis. Front. Pharmacol. 13:1019915

Xu L, Wang F and Luo F (2022), Rituximab for the treatment of connective tissue disease–associated interstitial lung disease: A systematic review and meta-analysis. Front. Pharmacol. 13:1019915

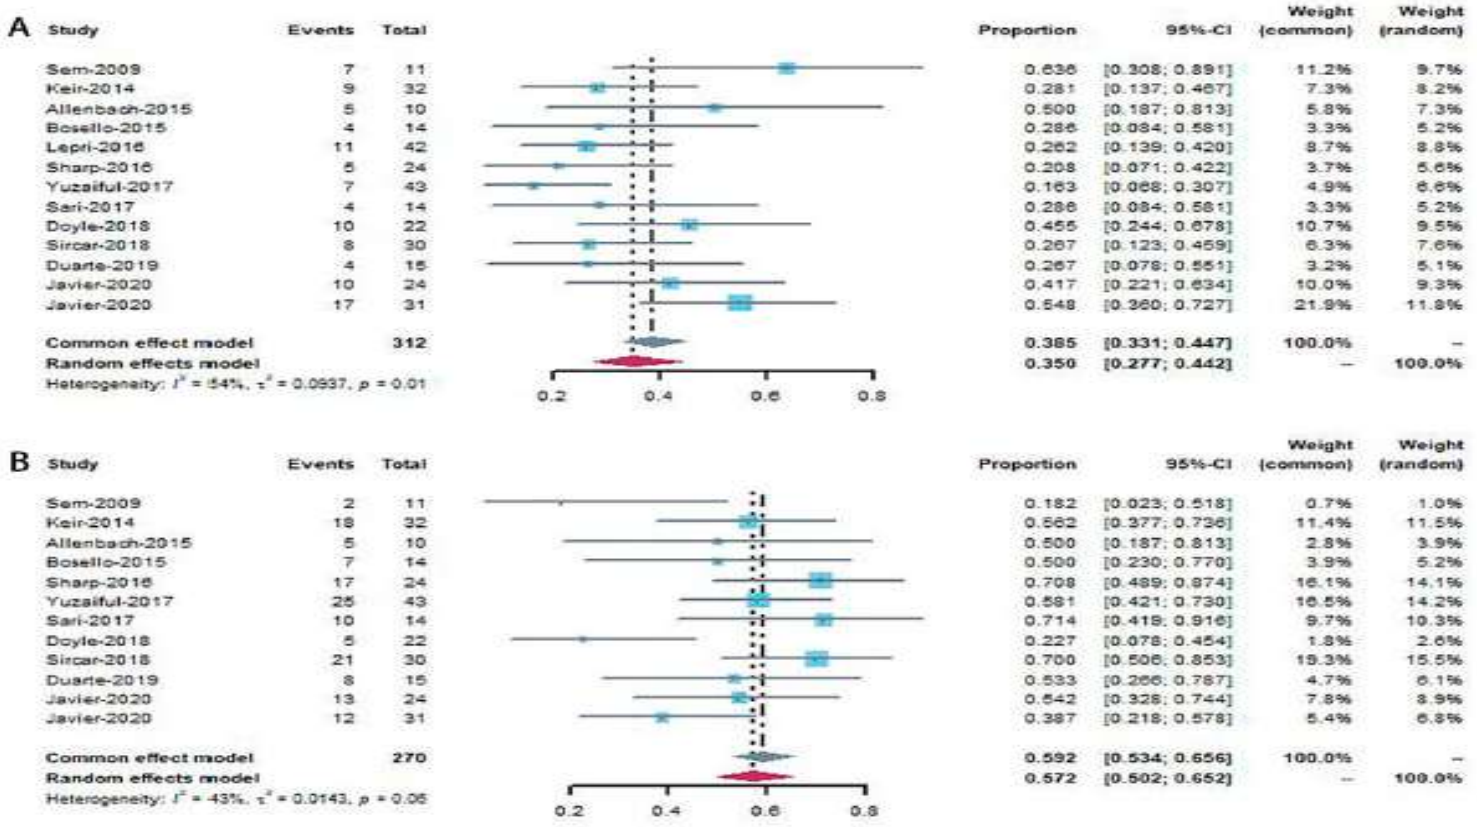

FIGURE 2
Forest plot showing improvement rate **(A)** and stable rate **(B)** to patients using rituximab.

Improvement - increase of ≥ 10% in forced vital capacity (FVC) and/or ≥ 15% in diffusing capacity of carbon monoxide (DLCO)

Worsening - decrease of ≥ 10% in FVC and/or ≥15% in DLCO, or death from progressive ILD

Stable - others that did not meet criteria for either worsening/improving

The improvement rate was estimated to be 35.0% in 312 patients with CTD-ILD, while the stable rate was 59.2%

Patients involved in this meta-analysis have not received antifibrotic treatment.

Dose is 1g intravenously separated by 1 to 2 weeks apart.

Usually preferred in refractory disease.

Cyclophosphamide

An alkylating agent causing cross-linkage of a variety of macromolecules, including DNA, producing cell death amongst resting and dividing lymphocytes.

Robust data is available for systemic sclerosis related ILD.

Dosing is either oral or intravenous

Intravenous is usually preferred, to avoid cumulative toxicity

Oral dosing is 2mg/kg/day with normal renal function

Iv dosing is 500-1000mg/m2 every 4 to 6 weeks.

A total duration of 6 months is usually given.

Cyclophosphamide for connective tissue disease–associated interstitial lung disease (Review)

Barnes H, Holland AE, Westall GP, Goh NSL, Glaspole IN

Meta-analysis of 4 studies

Three studies included only participants with systemic sclerosis, one study included participants with systemic sclerosis, dermatomyositis/ polymyositis, systemic lupus erythematosus (SLE), and rheumatoid arthritis (RA)

Subgroups are not separately analysed

BarnesH et. al., Cyclophosphamide for connective tissue disease–associated interstitial lung disease. Cochrane Database of Systematic Reviews 2018 (1): CD010908.

Figure 4. Forest plot of comparison: 1 Cyclophosphamide versus placebo, outcome: 1.1 FVC % predicted.

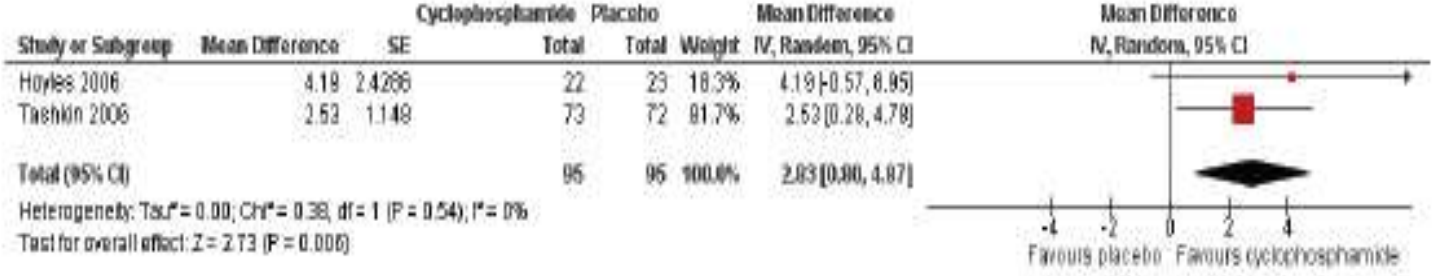

Figure 5. Forest plot of comparison: 1 Cyclophosphamide versus placebo, outcome: 1.2 DLCO % predicted.

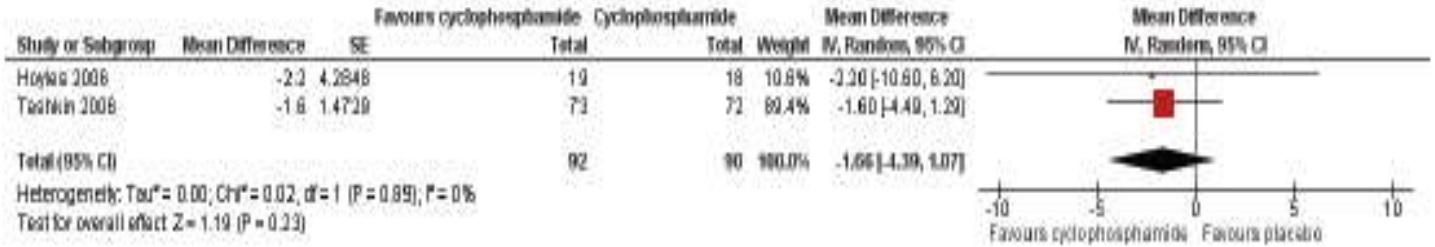

Figure 6. Forest plot of comparison: 2 Cyclophosphamide versus mycophenolate, outcome: 2.2 FVC % predicted at end of study.

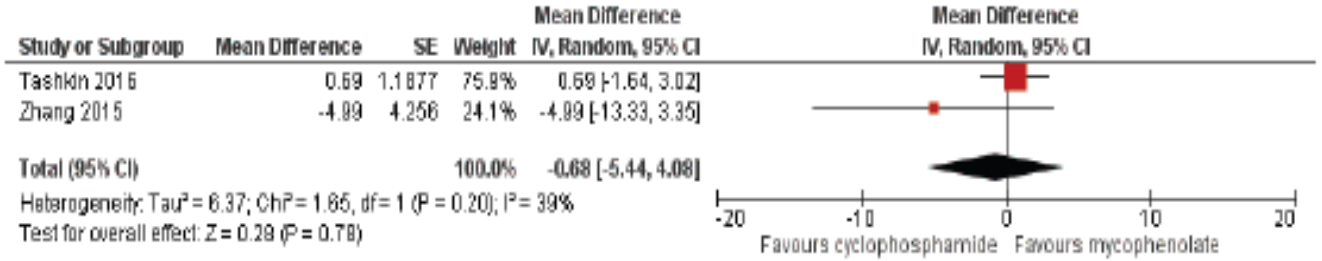

Figure 7. Forest plot of comparison: 2 Cyclophosphamide versus mycophenolate, outcome: 2.4 DLCO % predicted at end of study.

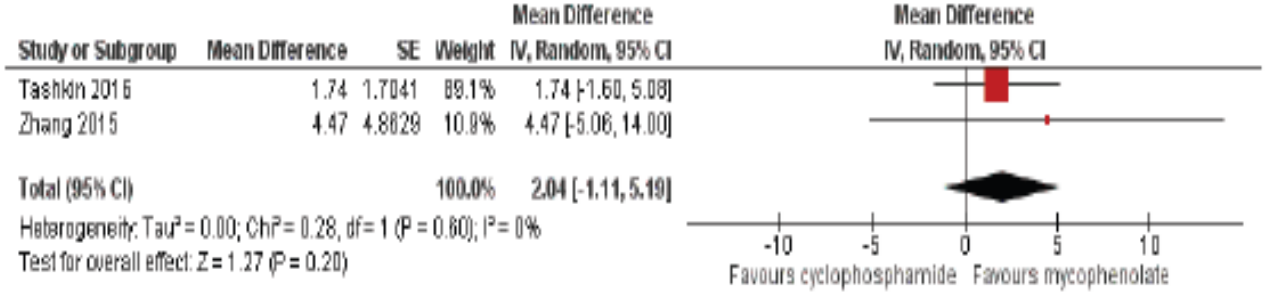

No mortality benefit when cyclophosphamide is compared with Mycophenolate mofetil.

Cyclophosphamide has higher incidence of side effects than mycophenolate mofetil.

Side effects of cyclophosphamide includes bone marrow suppression, hemorrhagic cystitis, bladder cancer (cumulative dose of 100 gm).

Which of the ILD can progress to PF-ILD at higher incidence?

TABLE 2 Underlying clinical diagnoses

Patients	165
Chronic fibrosing hypersensitivity pneumonitis	14 (8.5)
Idiopathic interstitial pneumonia	12 (7.3)
Unclassifiable ILD	52 (31.5)
Interstitial pneumonitis with autoimmune features	2 (1.2)
Autoimmune ILD	77 (46.7)
Rheumatoid arthritis-ILD	7 (4.2)
Systemic sclerosis-ILD	43 (26.1)
Dermatomyositis-ILD	12 (7.3)
Mixed connective tissue disease-ILD	10 (6.1)
Other autoimmune ILD[#]	5 (3.0)
Other ILDs[¶]	10 (6.1)

Data are presented as n or n (%). ILD: interstitial lung disease. [#]: Sjögren syndrome ILD (n=1), systemic lupus erythematosus (n=1), others (n=3); [¶]: exposure-related ILD (n=2), other fibrosing ILD (n=5), sarcoidosis (n=3).

Nasser M, Larrieu S, Si-Mohamed S, et al. Progressive fibrosing interstitial lung disease:a clinical cohort (the PROGRESS study). Eur Respir J 2021; 57: 2002718

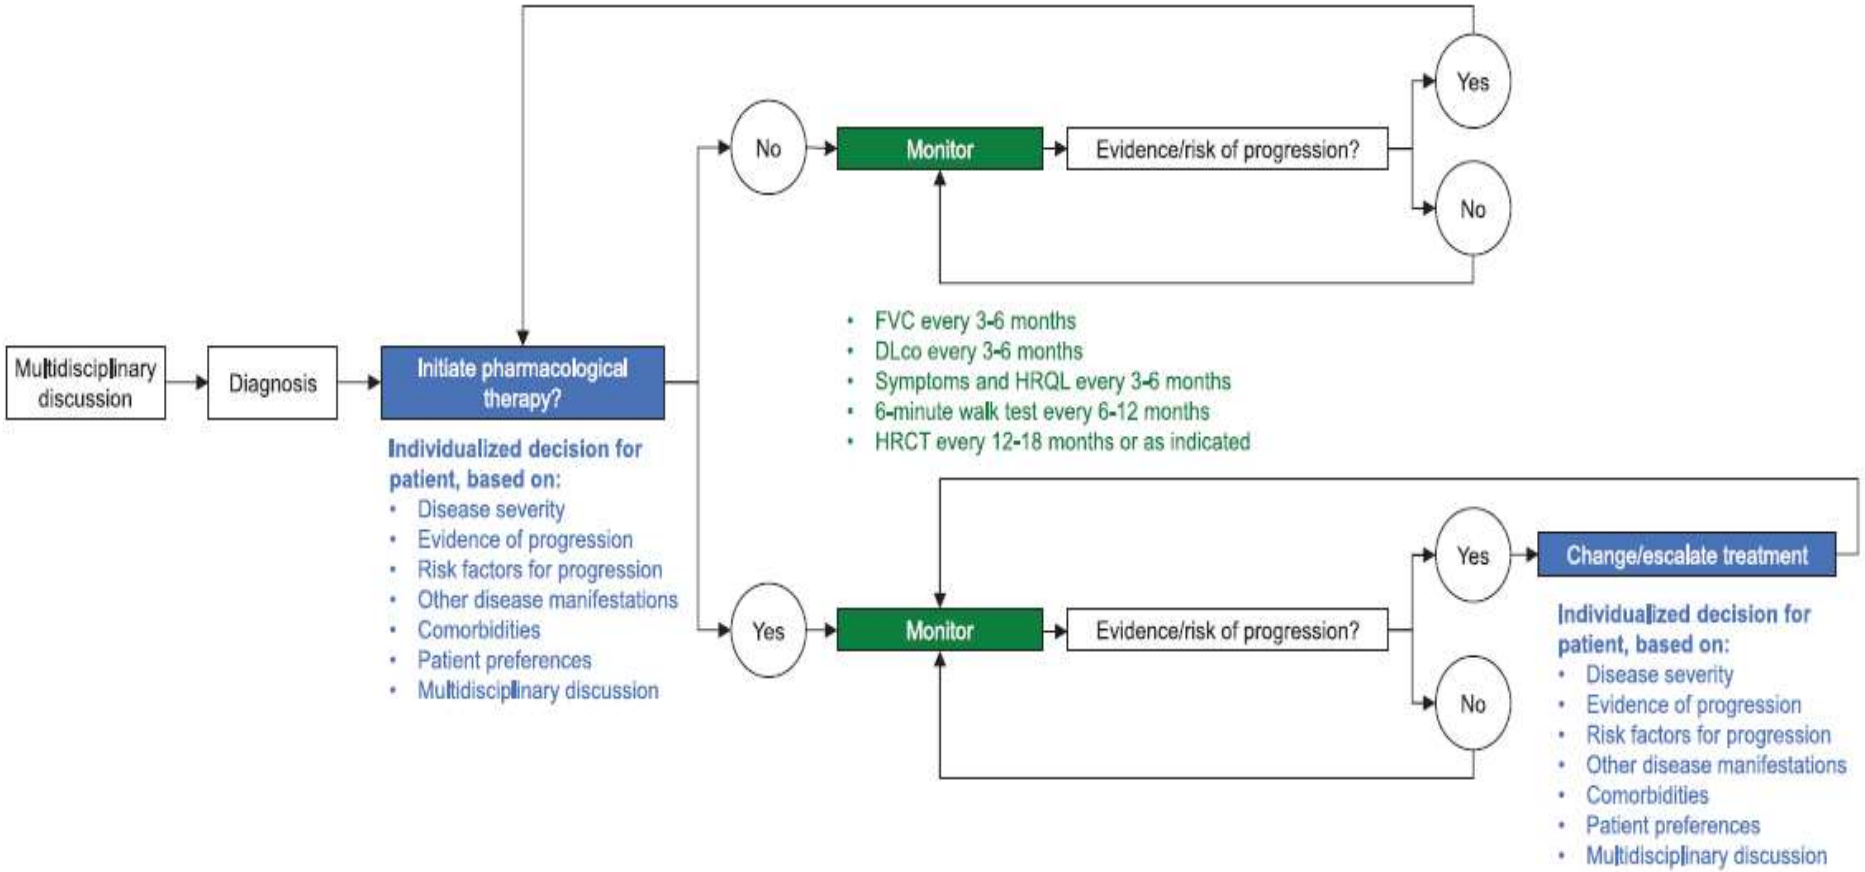
How to follow up patients of PF-ILD?



Anoop M. Nambiar et. al.,Ther Adv Respir Dis. 2021;15:17534666211039771

- Radiological UIP pattern progress faster than the non-UIP pattern.
- Fibrotic lesion in lung has -500HU.(normal lung -850HU)
- UIP pattern from non-IPF can be differentiated from IPF by signs like exuberent honeycombing, anterior upper lobe sign and straight edge sign. These usually occurs with CTD-ILD.

Abu Qubo A et al, The Role of Radiology in Progressive Fibrosing Interstitial Lung Disease. Front Med (Lausanne). 2022 13;8:679051.

Exuberent honeycombing sign

Anterior lobe sign

Chung JH et al, CT Features of the Usual Interstitial Pneumonia Pattern: Differentiating Connective Tissue Disease-Associated Interstitial Lung Disease From Idiopathic Pulmonary Fibrosis. AJR Am J Roentgenol. 2018;210(2):307-313.

Straight edge sign

Chung JH et al, CT Features of the Usual Interstitial Pneumonia Pattern: Differentiating Connective Tissue Disease-Associated Interstitial Lung Disease From Idiopathic Pulmonary Fibrosis. AJR Am J Roentgenol. 2018;210(2):307-313

For fibrosing ILDs other than IPF, the optimal sequence, combination and timing of use of immunosuppressants, nintedanib, and supportive therapies has not been established.

Oxygen therapy in ILD

Resting hypoxemia (Pao2 < 55 mm Hg);Moderately severe resting hypoxemia (Pao2 <60 mm Hg) with complications of chronic hypoxemia – becomes indication for long term oxygen therapy

Short term oxygen therapy has shown improvement in resting dyspnea. It has shown to increase the exercise capacity but not dyspnea during exercise.

Ambulatory oxygen therapy with portable oxygen cylinders(than portable compressed oxygen cylinders) may improve the quality of life in these patients.

Portable oxygen cylinders has limited use in severe exertional hypoxemia due to higher flow requirment.

Bell EC, Cox NS, Goh N, et al. Oxygen therapy for interstitial lung disease: a systematic review. Eur Respir Rev 2017; 26: 160080

Definitions of oxygen therapy used in ILD

- *Long-term oxygen therapy (LTOT)* in which oxygen is delivered for patients with chronic hypoxemia, for at least 15 hours daily.
- *Ambulatory oxygen therapy (AOT):* Oxygen supplementation during exercise and daily activities for patients who are not hypoxemic at rest but who develop hypoxemia on exercise.
- *Nocturnal oxygen therapy (NOT)* in which oxygen administered overnight alone with no oxygen therapy during daytime hours.
- *Short burst oxygen* in which a brief and intermittent oxygen supplementation used as needed in the absence of hypoxemia.
- *Palliative oxygen therapy (POT):* The use of oxygen for relieving breathlessness in advanced or life-limiting disease in the absence of known hypoxemia.

Shebl E, Modi P, Cates TD. Home Oxygen Therapy. 2022 Jul 4. In: StatPearls [Internet]. Treasure Island (FL): StatPearls Publishing; 2022.

Nocturnal desaturation is a independent predictor of mortality in ILD patients.
Nocturnal oxygen supplementation can be given in these populations.

Data for LTOT in ILD comes from COPD trials.

Yet H khor et. Al.,Curr Opin Pulm Med 2020, 26:464–469

Effect of ambulatory oxygen on quality of life for patients with fibrotic lung disease (AmbOx): a prospective, open-label, mixed-method, crossover randomised controlled trial

Summary

Background In fibrotic interstitial lung diseases, exertional breathlessness is strongly linked to health-related quality of life (HRQOL). Breathlessness is often associated with oxygen desaturation, but few data about the use of ambulatory oxygen in patients with fibrotic interstitial lung disease are available. We aimed to assess the effects of ambulatory oxygen on HRQOL in patients with interstitial lung disease with isolated exertional hypoxia.

Methods AmbOx was a prospective, open-label, mixed-method, crossover randomised controlled clinical trial done at three centres for interstitial lung disease in the UK. Eligible patients were aged 18 years or older, had fibrotic interstitial lung disease, were not hypoxic at rest but had a fall in transcutaneous arterial oxygen saturation to 88% or less on a screening visit 6-min walk test (6MWT), and had self-reported stable respiratory symptoms in the previous 2 weeks. Participants were randomly assigned (1:1) to either oxygen treatment or no oxygen treatment for 2 weeks, followed by crossover for another 2 weeks. Randomisation was by a computer-generated sequence of treatments randomly permuted in blocks of constant size (fixed size of ten). The primary outcome, which was assessed by intention to treat, was the change in total score on the King's Brief Interstitial Lung Disease questionnaire (K-BILD) after 2 weeks on oxygen compared with 2 weeks of no treatment. General linear models with treatment sequence as a fixed effect were used for analysis. Patient views were explored through semi-structured topic-guided interviews in a subgroup of participants. This study was registered with ClinicalTrials.gov, number NCT02286063, and is closed to new participants with all follow-up completed.

Findings Between Sept 10, 2014, and Oct 5, 2016, 84 patients were randomly assigned, 41 randomised to ambulatory oxygen first and 43 to no oxygen. 76 participants completed the trial. Compared with no oxygen, ambulatory oxygen was associated with significant improvements in total K-BILD scores (mean 55·5 [SD 13·8] on oxygen *vs* 51·8 [13·6] on no oxygen, mean difference adjusted for order of treatment 3·7 [95% CI 1·8 to 5·6]; p<0·0001), and scores in breathlessness and activity (mean difference 8·6 [95% CI 4·7 to 12·5]; p<0·0001) and chest symptoms (7·6 [1·9 to 13·2]; p=0·009) subdomains. However, the effect on the psychological subdomain was not significant (2·4 [−0·6 to 5·5]; p=0·12). The most common adverse events were upper respiratory tract infections (three in the oxygen group and one in the no-treatment group). Five serious adverse events, including two deaths (one in each group) occurred, but none were considered to be related to treatment.

Interpretation Ambulatory oxygen seemed to be associated with improved HRQOL in patients with interstitial lung disease with isolated exertional hypoxia and could be an effective intervention in this patient group, who have few therapeutic options. However, further studies are needed to confirm this finding.

Role of lung transplantation:

TABLE 1 Criteria for referral and listing for lung transplantation in patients with interstitial lung disease (ILD)

Timing of referral[#]	Timing of listing
Histopathological UIP	Hospitalisation for respiratory decline, pneumothorax or acute exacerbation
Radiographic probable or definite UIP pattern	Desaturation to <88% on 6MWT or >50 m decline in 6MWD over 6 months
FVC <80% or D_{LCO} <40% pred	Pulmonary hypertension on right heart catheterisation or echocardiography
Relative decline in pulmonary function over the past 2 years: FVC ⩾10% or D_{LCO} ⩾15% or FVC ⩾5% with symptomatic or radiographic progression	Absolute decline in pulmonary function over the past 6 months despite appropriate treatment: FVC >10% or D_{LCO} >10% or FVC >5% with radiographic progression
Any resting or exertional oxygen requirement	
For inflammatory ILDs, disease progression despite treatment	

Referral or listing should be considered if meeting any one criterion. UIP: usual interstitial pneumonia; FVC: forced vital capacity; D_{LCO}: diffusing capacity of the lung for carbon monoxide; 6MWT: 6-min walk test; 6MWD: 6-min walk distance. [#]: earlier referral is recommended for patients with connective tissue disease or familial idiopathic pulmonary fibrosis to address potential extrapulmonary manifestations. Reproduced and modified from [13] with permission.

Kapnadak SG, Raghu G. Lung transplantation for interstitial lung disease. Eur Respir Rev 2021; 30: 210017

Absolute contraindications
Lack of patient willingness or acceptance of transplant
Malignancy with high risk of death or recurrence
GFR <40 mL·min^{-1}·1.73 m^{-2} unless being considered for multi-organ transplant
Acute coronary syndrome within 30 days (excluding demand ischaemia)
Stroke within 30 days
Liver cirrhosis with portal hypertension or synthetic dysfunction unless being considered for multi-organ transplant
Acute liver failure
Acute renal failure with rising creatinine or on dialysis and low likelihood of recovery
Active extrapulmonary infection including septic shock
Active tuberculosis infection
HIV infection with detectable viral load
Severely limited functional status with poor rehabilitation potential
Progressive cognitive impairment
Repeated episodes of nonadherence without evidence of improvement
Active substance use or dependence including current tobacco use, vaping, marijuana smoking or intravenous drug use
Other severe uncontrolled medical condition expected to limit survival after transplant

TABLE 3 Common risk factors for adverse post-lung transplant outcomes in disease
Advanced age
Overweight status
Telomere biology disorders
Prior thoracic surgery
Limited functional status, deconditioning, frailty
Gastro-oesophageal reflux
High-risk atherosclerotic disease
Connective tissue disease manifestations
Corticosteroids, other immunosuppressants
Acute exacerbations
Active mechanical ventilation

TABLE 4 Morbidity rates in survivors at 5 years after lung transplantation for interstitial lung disease

	Idiopathic interstitial pneumonia % of survivors with listed diagnosis	Other interstitial lung diseases % of survivors with listed diagnosis
Hypertension	79.5	80.0
Creatinine >2.5 $mg \cdot dL^{-1}$	35.8	34.4
Chronic dialysis or renal transplant	2.7	2.7
Hyperlipidaemia	63.4	57.1
Diabetes	37.7	33.2

Data from the International Society for Heart and Lung Transplantation 2016 registry [143].

Research questions

- Best time for drug and non-drug interventions in PPF?
- Is there any evidence for early treatment delaying progression, reducing FVC decline?
- Impact of other interventions (pulmonary rehabilitation, oxygen therapy) on the survival of PPF?
- Is there any role of bio-markers in the early detection of PPF that could influence its management?
